Your Presentation Title

Your Name

Department or Institution

October 17, 2026

Outline

Introduction

Main ideas
- The mean
- Visual examples

Summary

Learning objectives

By the end of this presentation, you should be able to:

- Explain the central idea in your own words.
- Apply the method to a simple example.
- Identify the assumptions and limitations.

Guiding question: What problem are we trying to solve?

An equation and its interpretation

The mean of n observations is

$$\bar{x} = \frac{1}{n} \sum_{i=1}^{n} x_i.$$

Key idea

Each observation contributes equally to the average.

Example

For the observations 2, 4, and 6, the mean is 4[1].

[1] A. Author (2026). *Example Book Title*. Example Publisher

Calculating the mean

For the observations 2, 4, and 6:

$$\begin{aligned}\bar{x} &= \frac{1}{n}\sum_{i=1}^{n} x_i \\ &= \frac{2+4+6}{3} \\ &= 4\end{aligned}$$

Interpretation: The average of these three values is 4.

Text beside a figure

- Introduce the figure and its context.
- Explain the most important feature.
- State what the audience should remember.

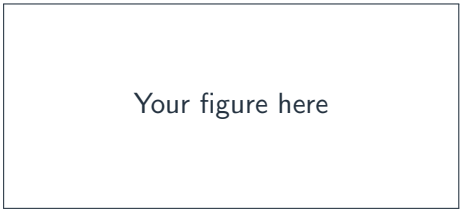

Figure 1: Replace with a descriptive caption.

Class discussion

Try it yourself

How does a single large observation affect the mean?

1. Find the mean of 2, 4, and 6.
2. Replace 6 with 24 and calculate it again.
3. Explain why the result changes.

Answer

The mean increases from 4 to 10 because it uses every value.

A common mistake

Check the calculation

A student computes $(2 + 4 + 6)/6$. Is this the mean?

Count the observations

Divide by the number of observations, not the largest value. Here there are three observations, so the mean is $12/3 = 4$.

Key takeaways

- Restate the main idea in one sentence.
- Connect the example to the broader topic.
- Suggest one question or next step to explore.

Questions and discussion

Questions and discussion

Replace with the one idea you want the audience to remember.
